

Chapter 10.1: UB-tree for Multidimensional Indexing

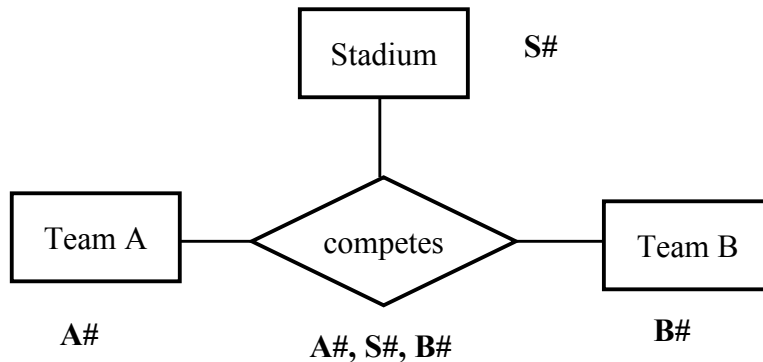

Chapter 6.1 Introduction

Note: all relational databases are multidimensional: a tuple in a relation with m attributes is considered as a point in m -dimensional space.

Prof. Bayer, DS 10.1 WS2001,
DWH, Ch.6, SS 2000

1

The relation *competes* resulting from the relationship is 3-dimensional just considering keys, even more with additional attributes

Prof. Bayer, DS 10.1 WS2001,
DWH, Ch.6, SS 2000

2

Geographic Data: weather stations:

(**X, Y, Z, time**, temp, humidity, wind velocity, ...)

Fundamental Problem: *how to partition multidimensional space for fast search, insertion, deletion?*

UB-tree relies on 3 basic concepts:

area

address

region

Prof. Bayer, DS 10.1 WS2001,
DWH, Ch.6, SS 2000

3

Areas and Addresses

Definition: An *area A* is a special subspace of the hypercube universe constructed as follows: partition the m -dim cube into 2^m subcubes of equal size and number them $1, 2, \dots, 2^m$

1. at level 1 take the first a_1 subcubes
 2. at level 2 take the first a_2 subcubes
of subcube a_1+1 of level 1
 3. at level 3 take the first a_3 subcubes
of subcube a_2+1 of level 2
- and in general:
- k. at level k take the first a_k subcubes
of subcube $a_{k-1}+1$ of level k-1
- etc.

Prof. Bayer, DS 10.1 WS2001,
DWH, Ch.6, SS 2000

4

Definition: The *address of an area A* is the sequence of subcube numbers

$$a_1.a_2. \dots .a_k = \text{alpha}(A) = \alpha(A)$$

according to the preceding definition.

Note: Lexicographic increase of address makes area bigger

Theorem: $\alpha < \beta \iff \text{Area}(\alpha) \subseteq \text{Area}(\beta)$

Concept of region

Def. If $\alpha < \beta$, then

$$\text{region}[\alpha : \beta] = \rho[\alpha : \beta] := \text{Area}(\beta) - \text{Area}(\alpha)$$

Note: for an increasing sequence of addresses

$$\alpha_1 < \alpha_2 < \alpha_3 < \dots < \alpha_k$$

we define corresponding regions

$$\rho_1 := (0 : \alpha_1] \quad \rho_2 := (\alpha_1 : \alpha_2] \quad \dots \quad \rho_k := (\alpha_{k-1} : \alpha_k]$$

which can also be represented as the increasing sequence:

$$\alpha_1 ; \alpha_2 ; \alpha_3 ; \dots ; \alpha_k$$

(which will later be stored in a B-tree index)

Alternative definition: an *area* is the set of points on an initial interval of the space filling Z-curve

Examples: areas with addresses

2 3.2.1 2.1.3.1.2

Idea 1: store data in region ρ_j on a disk page P_j

Idea 2: store addresses

$\alpha_1 ; \alpha_2 ; \alpha_3 ; \dots ; \alpha_k$

in a B-tree or B*-tree or Prefix B-tree

P_1, \dots, P_k are the leaves of the B-tree

Fundamental Question: *How to split spatial region, if the leaf page of a B-tree must be split?*

Points and Coordinates

point $p = (x_1, x_2, \dots, x_m)$

At a certain resolution, p is a small square (pixel)

Def: Address $\alpha(p)$ = address of that area, whose last point is p

Def: $\text{cart}(\alpha)$ = Cartesian coordinate of point p with address α

Lemma: $\text{cart}(\alpha(p)) = p$

$\text{cart}(\alpha(x_1, x_2, \dots, x_m)) = (x_1, x_2, \dots, x_m)$
